

Traffic Safety Basic Facts 2007

Urban areas

In 2005¹, 8.579 persons were killed in urban road traffic accidents in the EU-14² (EU-15 without Germany). This is 32,9% of all traffic accident fatalities in 2005. In the last decade, urban road fatalities have reduced by more than one quarter (27,1%), while the total number of fatalities has reduced slightly less (25,3%).

Urban road fatalities were reduced by more than 27% between 1996 and 2005.

Table 1 presents the number of fatalities in urban road accidents by country from 1996 to 2005. Given that the only data available for Estonia, Hungary and Poland are from 2005, these countries are not taken into account in the totals. Moreover, Malta has been excluded from the analysis and comparisons due to fact that this country does not distinguish inside from outside urban areas. Figure 1 shows the total number of fatalities within urban areas each year and the proportion of all fatalities that occurred within urban areas. Although the number of fatalities within urban areas has fallen, the proportion has hardly changed. The line is dashed for the years where the data are not available for all the countries.

Table 1: Urban road fatalities by country by year in EU-14, 1996-2005

¹ Using latest data available, i.e. 2005 for all countries except LU (2002), IE and NL (2003) and IT (2004). The data from EE, HU and PL are not considered.

² See table "Definition of EU-level and used Country abbreviations" on page 11.

In 2005, more than 8.500 persons died in road accidents inside urban areas in the EU-14. This corresponds to 32,9% of all the road traffic fatalities.

Figure 1: Number of urban road fatalities and proportion on total fatalities in EU-14, 1996-2005

Source: CARE Database / EC
Date of query: November 2007

The number of fatalities in urban road accidents has fallen since 1996. The percentage of all fatalities that occurred within urban areas, however, remained around 33%.

To compare the urban fatality data of the different countries, the respective population size has been taken into account (see Table 2). In 2005, 68,4 persons per million inhabitants died in urban road accidents in Greece, this rate is almost six times the Swedish rate of 12,2 (see Figure 2).

Table 2: Urban road fatalities per million inhabitants by country, 2005

From all the EU-17 countries, Spain is the one that shows the lowest ratio of urban road fatalities with respect to the total number of fatalities.

The proportion of the total number of fatalities in 2005 in each country of the EU-17 that occurred within urban areas is shown in Table 3. The proportion in Spain is less than 18% while in countries like Greece, Poland, Portugal or Italy it exceeds 40% (see Figure 3).

Table 3: Urban road fatalities as a percentage of total fatalities, 2005

	Urban road fatalities	Total fatalities	Ratio
BE	255	1.089	23,4%
DK	95	331	28,7%

In Poland and in Greece, almost half of the fatalities happen inside urban areas.

Age and gender

The percentage of the elderly fatalities in road accidents in 2005 is much higher inside urban areas than outside, as it may be observed in Figure 4. This could be explained by the fact that the elderly trips are usually short and mostly done as pedestrians, and because they do not often travel outside urban areas. The young citizens also have a higher percentage of fatalities inside urban areas than outside.

Figure 4: Inside/outside urban area fatality percentage by age group in EU-17, 2005³

Source: CARE Database / EC
Date of query: November 2007

³ Using latest data available, i.e. 2005 for all countries except LU (2002), IE and NL (2003) and IT (2004).

The percentage of the elderly fatalities is much higher inside urban areas.

More than 50% of the elderly fatalities in the United Kingdom, Italy, Greece and the Netherlands in 2005 took place inside urban areas. In Hungary and Poland the figure is over 65%. In Spain, only 27,7% of the elderly died inside urban areas (see Figure 5). Due to small numbers, Luxembourg has not been taken into account in the analysis.

** Data from 2003
*** Data from 2002

Source: CARE Database / EC
Date of query: November 2007

Figure 6 compares the proportion of fatalities by gender in urban and rural areas. The percentage of the female fatalities is higher in urban areas than in rural areas. Luxembourg and Portugal are the countries with the lowest percentage of female fatalities within urban area (see Figure 7).

Figure 6: Share of gender for urban and rural fatalities in EU-17, 2005³

Source: CARE Database / EC
Date of query: November 2007

Only 27,7% of the elderly fatalities in Spain in 2005 died inside urban areas.

The percentage of female fatalities is higher inside than outside urban areas.

Figure 7: Distribution of urban fatalities by gender, 2005

* Data from 2004
** Data from 2003
*** Data from 2002

Source: CARE Database / EC
Date of query: November 2007

Of the EU-17 countries, Ireland has the greatest percentage of urban fatalities who are female.

Type of road user

Table 4 shows the distribution of the fatalities by type of road user inside and outside urban areas in 2005 by countries as well as the EU-17 average. Inside urban areas, 53,1% of the fatalities are drivers and 33% are pedestrians. Outside urban areas, these percentages are 66,6% for the drivers and only 9,1% for pedestrians.

As it can be seen in the figure 8, in the Netherlands, 72,8% of the fatalities inside urban areas in 2005 (the data actually corresponds to 2003) were drivers, while in Estonia and Poland, the percentages are more balanced given that 37,8% (EE) and 38,4% (PL) were drivers and 46,7% (EE) and 46,3% (PL) were pedestrians.

Table 4: Inside/outside urban area fatalities by type of road user and by country, 2005

Junction

Table 5 shows that in the EU-15⁴ countries, there are more fatalities at urban junctions than at non-urban junctions. This is caused by the fact that most of the junctions are inside urban areas. Estonia, Ireland, Austria, Portugal, Finland and Sweden are the countries that have “unknown” cases. Sweden and Ireland have been removed from the table because the percentage of “unknown” they have is too high to be taken into account in the analysis.

Table 5: Fatalities in junction/no junction inside/outside urban areas by country, 2005

	Inside urban area			Outside urban area		
	Junction	No junction	Unknown	Junction	No junction	Unknown

* Data from 2004
** Data from 2003
*** Data from 2002

Source: CARE Database / EC
Date of query: November 2007

Inside urban areas, Greece is the country that presents the lowest percentage of junction fatalities with 12,5%. Estonia, Poland, Portugal and France also present a low percentage of junction fatalities (between 21 and 24%). On the other hand, more than one half of the fatalities in Denmark and the United Kingdom occur at junctions (see Figure 9). The Netherlands also has a high level of fatalities at junctions even though more than one half of the fatalities occur out of junctions.

⁴ The EU-15 represents the EU-17 countries except Sweden and Ireland, because the percentage of “unknown” they have is too high to be taken into account in the analysis.

The proportion of fatalities in junction inside urban areas is double the proportion of fatalities in junction outside urban areas.

Figure 9: Urban fatalities in junction/no junction by country, 2005

* Data from 2004
** Data from 2003
*** Data from 2002

Source: CARE Database / EC
Date of query: November 2007

In Denmark and in the United Kingdom, more than half of urban fatalities occur at junctions.

Day and Month

The distribution of the fatalities in the EU-17 countries in urban areas by day of the week is shown in Figure 10, also the distribution in non-urban areas. On working days, the percentage of fatalities is higher in urban than in non-urban areas, while the reverse is true at the weekend.

Figure 10: Distribution of fatalities by day of week in urban and non-urban areas in the EU-17, 2005³

Source: CARE Database / EC
Date of query: November 2007

During the weekends, the percentage of fatalities outside urban areas increases.

Figure 11 shows a comparison between the numbers of fatalities by month inside/outside urban areas. Even though the number of fatalities by month in 2005 has the same pattern inside and outside urban areas (with highest values outside urban areas), it is important to point out that the rise of the number of fatalities during the summer months is higher outside urban areas than inside. A possible reason could be that most people take holidays in the summer and then increase traffic outside urban areas. On the other hand, Figure 11 also shows that the lowest number of fatalities in urban areas occurs in February and April, followed by March.

Figure 11: Inside/outside urban area fatalities by month in EU-17, 2005³

Source: CARE Database / EC
Date of query: November 2007

The proportion of fatalities in urban areas is lower in the summer than in the winter.
